Introduction

Chapter 1

Markov Decision Processes

Definition 1.0.1. (Kernel) $(Y, \mathcal{A}_Y), (X, \mathcal{A}_X)$ measure spaces

$\lambda: X \times \mathcal{A}_Y \rightarrow \mathbb{R}$ is a (*probability kernel*) $: \iff \lambda(\cdot, A): x \mapsto \lambda(x, A)$ measurable

$\lambda(x, \cdot): A \mapsto \lambda(x, A)$ a (prob.) measure

Since we will interpret probability kernels as distributions over Y given a certain condition X , the notation $\lambda(\cdot | x) := \lambda(x, \cdot)$ helps this intuition.

Definition 1.0.2. (Markov Decision Process - MDP)

$\mathcal{M} = (\mathcal{X}, \mathcal{A}, \mathcal{P}_0)$, with:

\mathcal{X} countable (finite) set of states

\mathcal{A} countable (finite) set of actions

transition probability kernel

$$\begin{cases} \mathcal{X} \times \mathcal{A} \rightarrow \mu P(\mathcal{X} \times \mathbb{R}) \\ (x, a) \mapsto \mathcal{P}_0(\cdot | x, a) \end{cases}$$

$\mu P(\mathcal{X} \times \mathbb{R})$ the set of probability measures on $\mathcal{X} \times \mathbb{R}$,

\mathcal{X} represents the next states,

\mathbb{R} the payoffs

is a (*finite*) *Markov Decision Process*.

Together with a discount factor $\gamma \in (0, 1]$ it is a:

discounted reward MDP $\gamma < 1$

undiscounted reward MDP $\gamma = 1$

For $(Y_{(x,a)}, R_{(x,a)}) \sim \mathcal{P}_0(\cdot | x, a)$ a random variable, is

$$r(x, a) := \mathbb{E}[R_{(x,a)}] \quad \text{the immediate reward function}$$

An MDP is *evaluated* as follows:

1. Select the initial state X_0 an \mathcal{X} -valued random variable.
2. $(A_t, t \in \mathbb{N})$ action selection rules (behaviors) will be discussed later, for now simply assume \mathcal{A} -valued random variables.
3. Select inductively: $(X_{t+1}, R_{t+1}) \sim \mathcal{P}_0(\cdot | X_t, A_t)$ with the markov property, i.e.:

$$\begin{aligned} & \mathbb{P}[(X_{t+1}, R_{t+1}) = (x, r) | (X_t, A_t) = (x_t, a_t), \dots, (X_0, A_0) = (x_0, a_0)] \\ &= \mathbb{P}[(X_{t+1}, R_{t+1}) = (x, r) | (X_t, A_t) = (x_t, a_t)] \end{aligned}$$

resulting in the stochastic process $((X_t, A_t, R_{t+1}), t \geq 0)$, which allows to define the *return*:

$$\mathcal{R} := \sum_{t=0}^{\infty} \gamma^t R_{t+1}$$

Remark 1.0.3. $(X_{t+1}, R_{t+1}) \sim \mathcal{P}_0(\cdot \mid X_t, A_t)$ with the markov property is well defined, i.e.:

$\exists(X_{t+1}, R_{t+1})$ $\mathcal{X} \times \mathbb{R}$ -valued random variable :

$(X_{t+1}, R_{t+1}) \sim \mathcal{P}_0(\cdot \mid X_t, A_t)$ and satisfies the markov property

Proof. □

Remark 1.0.4.

1. From now on we assume that $\forall(x, a) \in \mathcal{X} \times \mathcal{A} : |R_{(x,a)}| \leq R \in \mathbb{R}$ almost surely. This also implies: $\|r\|_{\infty} = \sup_{(x,a) \in \mathcal{X} \times \mathcal{A}} |\mathbb{E}[R_{(x,a)}]| \leq R$

$$|\mathcal{R}| \leq \sum_{t=0}^{\infty} \gamma^t |R_{t+1}| \leq \frac{R}{1-\gamma} \text{ a.s.}$$

2. Sometimes not all actions make sense in all states. A simple fix would be to set the immediate reward functions for those actions very low, or (if possible) redirect them to the closest possible action.
A more formal approach would be to introduce an additional mapping, which assigns the set of admissible actions to each state $\mathcal{X} \rightarrow \mathcal{P}(\mathcal{A})$, or alternatively define a (binary) relation on $\mathcal{X} \times \mathcal{A}$.
3. If there is just one admissible action in every state, the MDP is equivalent to a normal Markov Process.
4. Instead of a transition probability kernel \mathcal{P}_0 , sometimes a *transition function* f with a and an exogenous random element D_t (e.g. Demand) is used to define the next state and reward: $(X_{t+1}, R_{t+1}) = f(X_t, A_t, D_t)$

Definition 1.0.5. $\mathcal{M} = (\mathcal{X}, \mathcal{A}, \mathcal{P}_0)$ a MDP

$x \in \mathcal{X}$ is a *terminal (absorbing)* state : $\iff \forall s \in \mathbb{N} : \mathbb{P}(X_{t+s} = x \mid X_t = x) = 1$

An MDP with such states is called *episodic*.

An *episode* is the random time period $(1, \dots, T)$ until a terminal state is reached.

Remark 1.0.6.

- The reward in a terminal state is by convention zero, i.e. x terminal state implies $\forall a \in \mathcal{A} : R_{(x,a)} = 0$.
- Episodic MDPs are often undiscounted

Definition 1.0.7. $\mathcal{M} = (\mathcal{X}, \mathcal{A}, \mathcal{P}_0)$ a MDP

An A_t selection-rule $\pi = (\pi_t, t \in \mathbb{N}_0)$ is called *behavior*, where

$$\pi_t: \begin{cases} ((\mathcal{X} \times \mathcal{A} \times \mathbb{R})^t \times \mathcal{X}) \times \mathcal{P}(\mathcal{A}) \rightarrow \mathbb{R} \\ (y, A) \mapsto \pi_t(A \mid y) \end{cases} \quad \text{is a probability kernel}$$

and $A_t \sim \pi_t(\cdot \mid (X_0, A_0, R_1), \dots, (X_{t-1}, A_{t-1}, R_t), X_t)$

Special cases:

1. *Deterministic stationary policies* specified with some abuse of notation:

$$\pi: \mathcal{X} \rightarrow \mathcal{A} \text{ with } A_t = \pi(X_t)$$

2. *Stochastic stationary policies* specified by:

$$\pi: \begin{cases} \mathcal{X} \times \mathcal{P}(\mathcal{A}) \rightarrow \mathbb{R} \\ (x, A) \mapsto \pi(A \mid x) \end{cases} \quad \text{with } A_t \sim \pi(\cdot \mid x)$$

Π_{stat} denotes the *set of (stoch.) stationary policies* (note that the deterministic policies are a subset of the stochastic policies)

Remark 1.0.8. A stationary policy induces a *time-homogenous* markov chain.

Definition 1.0.9. (Markov Reward Process - MRP)

Definition 1.0.10. $\mathcal{M} = (\mathcal{X}, \mathcal{A}, \mathcal{P}_0)$ MDP, π Behavior

Select X_0 such that $\forall x \in \mathcal{X} : \mathbb{P}(X_0 = x) > 0$ and evaluate the MDP with $((X_t, A_t, R_{t+1}), t \in \mathbb{N}_0)$ the resulting stoch. process.

$$V^\pi: \begin{cases} \mathcal{X} \rightarrow \mathbb{R} \\ x \mapsto \mathbb{E}[\mathcal{R} \mid X_0 = x] \end{cases} \quad \text{is the } \textit{value function} \text{ for } \pi^1$$

$$Q^\pi: \begin{cases} \mathcal{X} \times \mathcal{A} \rightarrow \mathbb{R} \\ (x, a) \mapsto \mathbb{E}[\mathcal{R} \mid X_0 = x, A_0 = a] \end{cases} \quad \text{is the } \textit{action value function} \text{ for } \pi^2$$

$$V^*: \begin{cases} \mathcal{X} \rightarrow \mathbb{R} \\ x \mapsto \sup_{\pi \text{ Behav.}} V^\pi(x) \end{cases} \quad \text{is the } \textit{optimal value function}$$

$$Q^*: \begin{cases} \mathcal{X} \times \mathcal{A} \rightarrow \mathbb{R} \\ (x, a) \mapsto \sup_{\pi \text{ Behav.}} Q^\pi(x, a) \end{cases} \quad \text{is the } \textit{optimal action value function}$$

²Well defined because $\mathbb{P}(X_0 = x) > 0$

²Well defined because $A_1 \sim \pi_1(\cdot \mid (x, a, r_0), x_1)$ is defined for all a regardless of π_0
